-----------	--------	--------------------------	------

CBC comprises of estimation of the cellular components of blood including RBCs, WBCs and Platelets. Mean corpuscular volume (MCV) is a measure of the size of the average RBC, MCH is a measure of the hemoglobin content of the average RBC and MCHC is the hemoglobin concentration per RBC. The red cell distribution width (RDW) is a measure of the degree of variation in RBC size (anisocytosis) and is helpful in distinguishing between some anemias. CBC examination is used as a screening tool to confirm a hematologic disorder, to establish or rule out a diagnosis, to detect an unsuspected hematologic disorder, or to monitor effects of radiation or chemotherapy. Abnormal results may be due to a primary disorder of the cell-producing organs or an underlying disease. Results should be interpreted in conjunction with the patient's clinical picture and appropriate additional testing performed.

WIDAL

While the definitive diagnosis of typhoid fever depends on the isolation of *S typhi* from blood, stools, urine or other body fluids, the role of the Widal test had been to increase the index of suspicion for the presence of typhoid fever by demonstrating a positive agglutination during the acute convalescent period of infection with evidence of a four-fold rise of antibody titre.

Please note that the test suffers from serious cross-reactivity with other infectious agents, it may produce false-positive results, leading to an over-diagnosis of typhoid fever.

The IgM somatic O antibody appears first and represents the initial serologic response in acute typhoid fever, while the IgG flagella H antibody usually develops more slowly but persists for longer.

In an individual with no prior exposure to *S typhi* infection (either lack of active infection or absence of passive immunisation), a higher than 1:80 or 1:160 titre on an initial single test, usually indicates towards exposure to typhoid fever. However, even these single high value titres in an endemic area like India where repeated exposures to *S typhi* may have occurred, do not have any clinical relevance in the absence of a positive isolate of the causal organism OR demonstration of rising titers of antibodies by testing 2 or more serum samples 1-2 weeks apart.

Researchers from different parts of India have reported that in normally healthy blood donors, the baseline titre for antibodies to "O" and "H" antigens of *Salmonella enterica* serotype typhi was 1:40 and hence, based on the above results, it could be recommended to use a cutoff level of >1:80 for a single antibody test titre. Similarly, baseline titre for antibody to H antigen of *Salmonella enterica* serotype paratyphi A and paratyphi B was 1:80 and the cutoff level was >= 1:160 for a single antibody test titre.

Urine routine examination and microscopy comprises of a set of screening tests that can detect some common diseases like urinary tract infections, kidney disorders, liver problems, diabetes or other metabolic conditions. Physical characteristics (colour and appearance), chemical composition (glucose, protein, ketone, blood, bilirubin and urobilinogen) and microscopic content (pus cells, epithelial cells, RBCs, casts and crystals) are analyzed and reported.
